# 1. Introduction

The progressive development of modern corporate finance theory has seen the incorporation of behavioural variables into the theoretical frameworks of financial economics, particularly as a complementing discourse to mitigate the challenges to the foundational concept of rationality in decision-making. A growing body of knowledge on behavioural finance has emerged through application of a dynamic modelling construct onto the 'traditionally' static modelling framework of neoclassical capital and market economy grand theorems on financing structure. Studies on the grand frameworks of modern financial economics have identified capital structure decisions as the most extensively researched area in corporate finance (Harris & Raviv, 1991). Various frameworks have been adopted to examine the underlying rationales, objectives, processes and mechanics behind capital structure determinations, yet there is limited consensus on how firms choose their capital structure (Lemmon, et al., 2014). This has induced postulations as to the relevance of behavioural variables in explaining the widely applied theoretical frameworks, such as capital structure irrelevance, pecking order, trade-off, agency cost, signalling mechanisms and asymmetric information (Myers & Majluf, 1984; Ross, 1977; Desai, et al., 2005). Studies on capital structure determinants have introduced specific theoretical conceptualisations and research frameworks (Titman & Wessels, 1988; Rajan & Zingales, 1995; Fama & French, 2002; Frank & Goval, 2004), and it is agreed that capital structure decisions and strategic choices deviate from the traditional neoclassical paradigms (Bilgehan, 2014). This has provided greater impetus for the study of how behavioural characteristics affect financing decision-making.

Recent studies have shown how biases such as overconfidence and optimism can affect corporate decisions (Azouzi & Jarboui, 2012) and that managers' overconfidence is positively and significantly related to leverage ratio when used as a proxy for capital structure (Malmendier et al., 2011; Cronqvist et al., 2012). Nevertheless, most studies on the relationships between managers' individual characteristics and firms' capital structure have focused on developed economies and more established capital markets, with limited research on wider capital markets. The present study examines behavioural variables as capital structure determinants for publicly listed firms (a wide capital market) in Indonesia (a developing/emerging economy).

### 2. Literature review

# 2.1 Rationality versus Irrationality in Corporate Decision-making

Rationality is the foundational and fundamental theoretical conceptualisation of decision-making (Vasiliou & Nikolaos, 2009) and is adopted in modelling assumptions such as efficient markets, symmetrical information, and tax neutrality. Studies on the grand frameworks of capital structure determinants have yielded significant derivative theories, which are typically adopted in testing capital structure efficiency and rationality considerations in financing and capital decisions. Trade-off theory (Kraus & Litzenberger, 1973) postulated the determination of an optimal capital structure, while 'pecking order' theory (Myers, 1984; Myers & Majluf, 1984) contradicted such a notion. The implicit assumption that investors and company managers will always act rationally is key for the operational functioning of the grand theorems of corporate finance and capital structure. This assumption does not consistently hold true, as evidenced by market anomalies, capital market imperfection, labour market imperfection and information asymmetry (Sanvicente, 2011). Extensive empirical research has been undertaken to explain the observed irrationality in financial and capital decisions. Initial conceptualisations of how psychological and behavioural variables might impact rational decision-making date back to Mackay's (1841) Extraordinary popular delusions and the madness of crowds. However, only much later did scholars expound more applicable frameworks for finance and economics (see Simon, 1955; Pratt, 1964; Raiffa, 1968; Kahneman & Tversky, 1979), such as behavioural finance, which assumed that investors are 'normal' rather than rational and that the market is inefficient. Accordingly, investors might not consistently adopt a mean-variance approach in constructing their portfolios and expected returns are a function of more than just risk-reward trade-offs (Stratman, 2008). Behavioural finance has its roots in earlier branches of social psychology. Initial significant works include The theory of moral sentiments (1759) and The wealth of nations (1776) by Adam Smith, who argued that there is an 'invisible hand' (moral compass) guiding individuals in decision-making, and Jeremy Bentham's (1789) framework on the psychological aspects of utility functions. These scholars laid the foundational theme of the role of human psychology in influencing economic behaviour, but this aspect of their works was not revisited until the early 20th century.

#### 2.2 Capital Structure Irrelevance Theory

Modigliani and Miller's (1958) capital structure irrelevance theory (the Modigliani–Miller Proposition-I or MM-I) is the basis for modern capital structure theories. MM-I is generally perceived as theoretically sound but based on unrealistic assumptions (e.g., a world without tax; see Abeywardhana, 2017). Following important refinements by Hirshleifer (1966) and Stiglitz (1969), Modigliani and Miller (1963) incorporated tax effects on the cost of capital and firm value assumptions in their model (MM-II). In the face of corporate taxes, the value of a firm increases with leverage due to tax shielding, indicating an optimum level where such shielding benefits would be maximised.

#### 2.3 Pecking Order Theory

Pecking order theory postulates that there is a latent preference for companies to prioritise internal financing rather than utilising debt capital, while equity raising/issuance is least preferred (Abeywardhana, 2017). This is supported by Al-Tally (2014). Firms borrow more when internally generated funds are insufficient to meet investment needs (Shyam-Sunder & Myers, 1999). Firms with higher profits and growth opportunities will use less debt capital, with the company's debt ratio representing the accumulation of external financing as the company reaches an optimal debt ratio (Myers, 2001). Under this framework, Harris and Raviv (1991) suggested that capital structure decisions are intended to eliminate inefficiencies caused by information asymmetry. Firms avoid capital market issuance due to information asymmetry and separation of ownership (Myers, 2001). Corporate debt issues signal to the market that a company is remarkable and its management is not afraid of debt financing (Frydenberg, 2004). Studies have offered inconsistent conclusions on significance of the pecking order framework for companies' capital structure. Fama and French (2002) argued that optimal capital structure can be identified through the benefits of debt interest reduction, bankruptcy costs and agency costs.

### 2.4 Trade-off Theory

Arnold (2008) demonstrated how an increase in capital debt affects the value of a firm; as the weighted average cost of capital of a company's leverage structure decreases until the company reaches its optimal gearing level, the cost of financial pressure increases along with the level of debt. This is consistent with Miller's (1988) findings that the optimal debt-to-

equity ratio reflects the highest possible tax shield that can be enjoyed by the company; this then increases shareholder wealth. Under trade-off theory, the cost of debt is associated with the direct and indirect costs of bankruptcy (see Bradley et al., 1984).

# 2.5 Market Timing

Firms decide on the 'timing' of the issuance of new equities and debts based on the perceived mispricing of their shares (Baker & Wurgler, 2002). Firms are expected to favour issuance of new equities when their stock prices are high, and vice versa. Accordingly, stock price fluctuations affect firms' financing decisions and, ultimately, influence capital structure (Baker & Wurgler, 2002). This implies that change in capital structure is sustained by durable market timing (Bessler et al., 2008) and that, conceptually, capital structure can be seen as the direct consequence of the cumulative outcome of prior periods' attempts at timing the equity market, with the gearing ratio is negatively related to past stock returns (Bessler & David, 2004). However, Hovakimian (2006) revealed that market timing does not significantly affect companies' long-term capital structure, and Alti (2006) indicated that the impact of market-timing efforts will completely fade within two years. Kisgen (2006) posited that capital structure decisions will change based on the costs and benefits of different rating levels of financing.

# 2.6 Behavioural Finance

Tversky and Kahneman (1979) introduced prospect theory to explain how behavioural variables relate to financial and economic considerations, laying the foundation for behavioural finance theory. Pompian (2011) categorised behavioural biases into cognitive and emotional biases. Cognitive biases include overconfidence, representativeness, anchoring and adjustment, framing, cognitive dissonance, availability, and mental accounting. Emotional biases include endowment bias, loss aversion, optimism and status quo. Optimistic managers prefer to use the pecking order approach in capital structure decisions, while overconfident managers exhibit debt-funding bias in such decisions. It has been empirically demonstrated that CEOs' characteristics and risk preference influence corporate leverage policy (Malmendier et al., 2011; Chen, et al., 2014) and managers' characteristics influence capital structure decisions (Armstrong et al., 2010; Huang & Kisgen, 2013; Serfling, 2014; Faccio et al., 2016; Li et al., 2017).

# Overconfidence

Odean (1998) defined overconfidence as the tendency of investors to overestimate the precision and relevance of their knowledge about the value of a security. Overconfidence is among the most researched biases and there is a wealth of empirical findings. Overconfidence is empirically proven to be widespread in the corporate world (De Bondt & Thaler, 1995; Malmendier & Tate, 2005). CEOs' and management's overconfidence has been shown to have negative (Heaton, 2002; Malmendier & Tate, 2005; Benson & Ziedonis, 2010; Ben-David et al., 2013; Shu et al., 2013; Aghazadeh et al., 2018) and positive (Hirshleifer et al., 2012) effects on firms' capital structure and value.

# Optimism

Heifetzy and Spiegel (2001), Germain et al. (2005) and Barone-Adesi et al. (2012) undertook substantial research on optimism as a heuristic bias within the context of financial economics. Optimism (pessimism) is among the greatest influencing biases—being principally driven and guided by past returns, it has direct impacts on investors' return expectations, return tolerance and risk perceptions (Hoffmann & Post, 2012) and significantly influences capital structure decisions (Abdeldayem & Sedeek, 2018).

# 2.7 Demographic Characteristics and Attributes

Top management teams (TMTs) are considered a visible representation of an organisation's workforce and the structural proxy for otherwise unobservable characteristics of human resources and culture (Sørensen, 2000). Both Pfeffer (1983) and Hambrick and Mason (1984) argued that TMTs' background characteristics could be used to predict behaviours and firm outcomes. A resulting large body of empirical research has substantively linked aggregate measures of team composition (e.g., functional heterogeneity, age diversity and tenure diversity) to firm-level outcomes. Upper echelons perspective has increasingly moved towards examining social psychological processes, individual perceptions and beliefs, contextually linked demographic variables and team-level variables (Jackson et al., 2003; Finkelstein et al., 2009; Nielsen, 2009). Contrasting schools of thoughts have emerged, with some questioning the empirical basis for focusing on 'simplistic' demographic variables and stating, 'we do not need "yet another study that examines the main effect of top management team's demographic effects on another organisational outcome" ' (Carpenter et al., 2004: 770). However, important empirical and theoretical insights have been provided by studies of demographic effects on corporate results. Having explored the limitations of past empirical findings on TMTs and organisational performance, the present study aims to better model the relationships between top managements' attributes, their impacts on strategic decision-making and the eventual impacts on capital structure determinations.

# 3. Research hypotheses

As previously discussed, prior empirical evidence suggests that managerial overconfidence and optimism can be important determinants of firms' capital structure (Barros & Da Silveira, 2007). Accordingly, the following hypotheses are introduced:

**Hypothesis 1:** Capital structure is positively influenced by overconfidence, as a behavioural bias that impacts on the capital structure decisions.

**Hypothesis 2:** Capital structure is positively influenced by optimism, as a behavioural bias that impacts on capital structure decisions.

The choice of information used in making decisions results in an information frame that affects decision-making (Kahneman & Tversky, 1979; Shefrin, 2000; Pompian, 2011). Based on this, the following hypothesis is introduced:

#### Hypothesis 3: Capital structure preference is framed by relevant information.

As previously discussed, prior studies have empirically proved that: 1) managerial traits explain the remaining variations of the traditional capital structure model, 2) personal portfolio choices are directly influenced by CEOs' and/or CFOs' behavioural biases and 3) formative experiences have a significant impact on decision-making. Based on this, the following hypothesis is introduced:

**Hypothesis 4:** Management's (CEOs/CFOs)' demographic attributes as moderating variables modify the relationship between overconfidence and optimism to capital structure decisions.

#### 4. Research method

#### 4.1 Collected Data

This study collected data from survey responses from CEOs and CFOs of public corporations (Tbks) listed on the Indonesian Stock Exchange (IDX; Bursa Efek Indonesia, BEI). The IDX provided the contact details of over 500 Tbks. Survey questionnaires were distributed to Tbks using Google Forms. This study excluded responses from banking and insurance and public utility firms, whose capital structures and equity formations are specifically regulated and mandated to comply with certain prescribed corporate entity and governance structures that practically and directly restrict their options of accessing financial and equity markets. Fifty fully completed surveys were considered suitable for the intended statistical analysis and measurement. Respondents represented the following industry sectors: agribusiness and forestry = 12%; real estate = 12%; basic industry and chemicals = 14%; consumer goods = 12%; transportation and infrastructure = 12%; mining = 14%; miscellaneous industry = 8%; and trade service and investment = 16%.

#### 4.2 Research model

Model I, to test and validate Hypotheses 1, 2 and 3:

$$\mathbf{D} = \boldsymbol{\beta}_{O} CONF_{1} + \boldsymbol{\beta}_{1} CONF2 + \boldsymbol{\beta}_{2} CONF_{3} + \boldsymbol{\beta}_{3} OPT + \boldsymbol{\beta}_{4} FE_{1} + \boldsymbol{\beta}_{5} FE_{2} + \boldsymbol{\beta}_{6} FE_{3} + \boldsymbol{\beta}_{7} FE_{4} + \boldsymbol{\beta}_{8} FE_{5},$$

where:

D =Capital Structure (Leverage Ratio as the proxy) CONF1 =Overconfidence 1; Delusion of being in control CONF2 =Overconfidence 2; An extensive level of commitment to a positive outcome CONF3 =Overconfidence 3; Vague parameters for comparison of performance OPT =Optimism FE1 =Framing Effect 1; Information: trade-off theory; industrial capital structure; credit rating; takeover risk FE2 =Framing Effect 2; Information: signalling theory; lower cost of debt; market timing theory; close banking relationships FE3 =Framing Effect 3; Information: average past P/E ratio FE4 =Framing Effect 4; Information: past credit rating FE5 =Framing Effect 5; Information: past market timing

Model II, to test and validate Hypothesis 4, with demographic attributes construct (constrained form):

 $D = \beta_{19}CONF1 + \beta_{20}CONF2 + \beta_{21}CONF3 + \beta_{22}FE1 + \beta_{23}FE2 + \beta_{24}FE3 + \beta_{25}FE4 + \beta_{26}FE5 + \beta_{27}OPT + \beta_{28}DM + \beta_{29}DM^*CONF1 + \beta_{30}DM^*CONF2 + \beta_{31}DM^*CONF3 + \beta_{32}DM^*OPT.$ 

D =Capital Structure (Leverage Ratio as the proxy) *CONF1* = Overconfidence 1; Delusion of being in control CONF2 = Overconfidence 2; An extensive level of commitment to a positive outcome CONF3 = Overconfidence 3; Vague parameters for comparison of performance FE1 = Framing Effect 1; Information: trade-off theory; industrial capital structure; credit rating; takeover risk FE2 = Framing Effect 2; Information: signalling theory; lower cost of debt; market timing theory; close banking relationships FE3 = Framing Effect 3; Information: average past P/E ratio *FE4* = Framing Effect 4; Information: past credit rating FE5 = Framing Effect 5; Information: past market timing OPT = OptimismDM = Demography Attributes DM\*CONF1 = Demographic Attributes interacted CONF1 DM\*CONF2 = Demographic Attributes interacted CONF2 DM\*CONF3 = Demographic Attributes interacted CONF3 DM\*OPT = Demographic Attributes interacted OPT

Model II, with demographic attributes construct (unconstrained form):

 $D = \beta_9 CONF1 + \beta_{10} CONF2 + \beta_{11} CONF3 + \beta_{12} FE1 + \beta_{13} FE2 + \beta_{14} FE3 + \beta_{15} FE4 + \beta_{16} FE5 + \beta_{17} OPT + \beta_{18} DM$ 

where:

D =Capital structure (leverage ratio as the proxy)

*CONF1* = Overconfidence 1; Delusion of being in control

CONF2 = Overconfidence 2; An extensive level of commitment to a positive outcome

*CONF3* = Overconfidence 3; Vague parameters for comparison of performance

FE1 = Framing Effect 1; Information: trade-off theory; industrial capital structure; credit rating; takeover risk

FE2 = Framing Effect 2; Information: signalling theory; lower cost of debt; market timing theory; close banking relationships

FE3 = Framing Effect 3; Information: average past P/E ratio

*FE4* = Framing Effect 4; Information: past credit rating

*FE5* = Framing Effect 5; information: past market timing

OPT = Optimism

DM = Demography attributes

Measurement variables. Independent variable:

**Capital structure** 

The value of the leveraged firm is equal to the company's unobserved value. Managers' choose the composition of debt to equity (Modigliani & Miller, 1958).

Dependent variables:

Overconfidence variable (Malmendier & Tate, 2005)
CONF1 = delusion of being in control
CONF2 = an extensive level of commitment to a positive outcome
CONF3 = vague parameters for comparison of performance
Optimism variable (Hoffmann & Post, 2012).
OPT = Return expectations, variance tolerance, risks perceptions

Framing effect variables:

*FE1* = Information: trade-off theory; industrial capital structure; credit rating; takeover risk

FE2 = Information: signalling theory; lower cost of debt; market timing theory; close relationships to bank

FE3 = Information: average past P/E ratio

*FE4* = Information: past credit rating

*FE5* = Information: past market timing

Moderating variables:

Age		
Gender		
Education		
Professional experience		

Sample size. Madhuri Thakur's formula (a refinement of Cochran's widely applied sampling error formula) was used to determine the appropriate and adequate sample size:

Sample Size 
$$n = N \times [Z^2 \times p \times (1-p)/e^2] / [N-1+(Z^2 \times p \times (1-p)/e^2]]$$

where:

N = Population size

Z = Critical value of the normal distribution at the required confidence level

*p* = Sample proportion

e = Margin of error

Population (N)	700
Critical value (95% CI) (Z)	1.96
Margin of error (e)	0.05
Sample proportion (uncertain)	0.5
Sample proportion ( <i>p</i> )	0.05
Sample size ( <i>n</i> )	47.17057

The sample size (n = 50) was thus determined to be appropriate and adequate for the intended statistical analysis. The collected data were analysed using partial least squares structural equation modelling, appropriate for statistically processing smaller (<100) sample sizes. The results are presented in Table 1. Full statistical summaries are in Appendix A.

Results of Model I analysis.

- Overconfidence only has 7.7% influence on management's (CEOs/CFOs) capital structure decision-making. Management's elevated level of confidence and inert belief in the appropriateness and suitability of their capital structure decisions (CONF2) account for 11.7% influence, exerting the highest level of direct positive influence on management's capital structure decision-making among the CONF indicators. Overconfidence deriving from management's propensity to undertake unilateral decision-making (CONF1) exerts –1.3% influence. Overconfidence stemming from management's overestimation of the superiority of their decision-making (CONF3) accounts for -2.7% influence. Optimism exerts 3.2% influence.
- 2. Behavioural traits, as affected by certain framing effects, are empirically proven to be consistent with the frameworks of trade-off theory, industrial capital structure, credit rating and takeover risk (*FE1*). *FE1* accounts for 13.3% influence on capital structure decision-making, exerting the highest level of influence among the model variables. This observation is consistent with prior literature on how related frameworks impact capital structure determinations. Management's capital structure decision-making is expected to be founded on such notions, as the ideal capital structure is the result of the trade-off between tax savings, relief and efficiency deriving from debt financing viz-a-viz the potential financial distress from a highly leveraged financing model. Industrial capital structure, credit rating and takeover risk considerations are also important framing information, which are empirically proven to influence capital structure decision-making. Framing effects deriving from signalling theory, lower cost of debt, market timing theory and close banking relationships are determined to have only 0.1% influence on capital structure decisions. Framing

128

#### D. R. Lim et al. / Accounting 8 (2022)

effects arising from heightened referencing against comparative financial performance metrics, such as the P/E ratio (as linked to agency theory, hence reflective of expectations on opportunity growth), account for 0.0% influence. Framing effects stemming from due consideration of creditworthiness position account for 0.3% influence.

- 3. Sampled management's (CEOs/CFOs) capital structure decision-making appears to not be significantly influenced by credit rating status and information on corporate creditworthiness. This is further confirmed by survey responses clearly indicating preference for bank loans rather than issuance of corporate bonds, despite the publicly listed firm status of their companies, which would be advantageous for the credit rating process. This indicates that the framing effect from credit rating (*FE4*) does not significantly influence capital structure determinations by Indonesian Tbks. Only ~10% of the sampled Tbks have issued corporate bonds, and this, on average, accounts for a small percentage (10–30%) of their long-term debt. Of the 727 companies publicly listed on the IDX as at the end of 2020, only 49 (6.7%; primarily the larger-capped and blue-chip firms) have issued corporate bonds.
- 4. Framing effects from market timing information have 3.2% influence on capital structure decision-making.
- 5. Framing effects deriving from various relevant financial and share performance information, available market comparable data, and sector and peer group benchmarks collectively exert 18.3% influence on capital structure decision-making.

### Conclusions from statistical testing on Model I.

Behavioural traits as modelled in this research are statistically validated to exert 29.2% influence on the capital structure decision-making by the sampled management (CEOs/CFOs). Accordingly, it can be concluded that behavioural traits and attributes do not significantly influence and are not determinants of capital structure decision-making for Indonesian Tbks.

Hypotheses testing results: Hypotheses 1, 2 and 3 are disproved (null hypothesis is rejected).

# Results of Model II analysis: Demographic attributes (unconstrained form).

- 1. Model II (unconstrained form), with the inclusion of variables for demographic attributes, was statistically validated for representing the influence of overconfidence, optimism, framing effect and demographic attributes on capital structure decision-making.
- 2. Under unmoderated equation modelling, the *DM* (demographic attributes) variables (age, gender, professional experience and education) are statistically determined to significantly (15.8%) influence the sampled management's (CEOs/CFOs) capital structure decision-making.
- 3. While statistical testing confirmed the demographic attributes are determinants of capital structure, the variables (overconfidence, optimism, framing effect and demographic attributes) were found to collectively only exert 38.9% influence on management's capital structure decision-making. This indicates that other variables yet to be incorporated into Model II have the power to explain the remaining 61.1% influence on management's capital structure decisions.
- Results of Model II analysis: Demographic attributes (constrained form) as moderators of the influence of overconfidence and optimism on capital structure.
- Statistical measurement shows that DM does not significantly moderate CONF and OPT in regard to capital structure decision-making (p > 0.05). Demographic attributes were not statistically determined to mediate overconfidence and optimism in influencing capital structure determinations.

Conclusions from statistical testing on Model II.

Statistical analysis confirmed that demographic attributes (*DM*) are determinants of capital structure, significantly influencing (15.82%) management's (CEOs and CFOs) capital structure decisions. However, *DM* was statistically determined to exert insignificant moderating power on the behavioural traits of overconfidence and optimism in their respective and combined influence on capital structure (*D*) decisions. Despite exerting 14% influence on the endogenous capital structure (*D*) variable, statistical measures do not suggest that the *DM* moderator will always and significantly influence management's capital structure decision-making.

Hypothesis testing result: Hypothesis 4 is disproved (null hypothesis is rejected).

# 5. Discussion

# 5.1 Overconfidence and Optimism

The general premise that management's decision-making, including decisions on capital structure, is influenced by the behavioural traits of overconfidence and optimism was statistically determined and validated (in Model I and Model II). This appears to support the notion that management's latent tendency to overestimate their competency and the superiority of their decisions is prevalent among the upper echelon of management in general.

The sampled management (CEOs/CFOs) was statistically determined to not be consistently and substantially influenced by the behavioural traits of overconfidence and optimism in their capital structure decisions. This observation was validated despite a portion (14.5%) of the sampled Tbks being public corporations founded, operated and controlled by successful entrepreneurs and their associated business groups. Several prior studies have concluded that entrepreneurs, founders and business owners possess higher overconfidence levels compared to managers and that this behavioural trait directly influences decision-making (see, e.g., Busenitz & Barney. 1997). In the present study, the sampled management (CEOs/CFOs) was found to possess these behavioural inclinations at a comparatively lower level. Nevertheless, the behavioural traits of overconfidence and optimism were not consistent and significant determinants of capital structure.

In a corporate setting, it is suggested that the degree of ignorance/incomplete understanding/overconfidence should be diminished by the general and wide availability of data and information pertaining to a specific company, investment or project. Management (CEOs/CFOs) is expected to rely on such data, as opposed to 'gut feel' and confidence, in decisionmaking. The present study's results suggest that comprehensive and relevant information and data are considered by the sampled Tbks' management (CEOs/CFOs) in capital structure decisions and are validated determinants of capital structure. However, the proposed models suggest that other factors and determinants have more influence on capital structure than overconfidence, optimism and framing effects from information. Survey responses suggested that, in any capital structure decisions, the sampled management considered relevant information and data (including project- or investment-specific data), broader datasets concerning sectoral and competitive benchmarks, and pertinent macro indicators. The implications of pecking order theory appear to be validated, as the results indicate a consistent lower level of preference for debt issuance among the sampled Tbks. Prior experience of financial and operational difficulties resulting from market shocks and macroeconomic malaise appear to shape the conservative mindset of Tbks' management (CEOs/CFOs) in prioritising internal sources of financing and equity capital, despite any influence of overconfidence. The typical determinants of capital structure (as modelled in this study) are not consistently significant in influencing management's capital structure decisionmaking. It can be inferred that the sampled management is likely to opt for delaying investments and projects if internal sources of capital are insufficient, rather than aggressively raising debt. The behavioural trait of optimism is statistically determined to have a moderate influence on the sampled management's capital structure decision-making and empirically proven to influence their utilisation of equity funding sources (preferring obtainment of loans and straight debts, rather than issuance of corporate bonds, when debt funding is required). The construct of market timing influence is statistically validated to have a moderate influence on capital structure decision-making, pointing to the preference for equity in the capital structure.

The above observations suggest that existing banking relationships may significantly influence the sampled management's (CEOs/CFOs) capital structure decisions, beyond the influence of the capital structure determinants modelled and tested in this study. The prevalence of business group or conglomeration structures among the IDX-listed Tbks may help explain this. A business group structure might provide a greater level of comfort to bankers in extending various debt accommodations, and, if controlled by a successful and creditworthy founder or entrepreneur, would provide a higher level of comfort to creditors (given the perception that such figurehead businesspeople would not risk their reputation). Entrepreneurs and founders might also value enduring banking relationships, expecting that this would shield the business from aggressive loan enforcements during times of financial distress and increase the likelihood of negotiating workable loan restructuring. For Indonesian public limited companies, such a perception of mutual benefits was likely solidified through experiences such as the 1997/1998 Asian Financial Crisis, 2008/2009 Global Financial Crisis and EM Currency Shocks of 2013/2014. The behavioural traits of overconfidence and optimism did not positively signal management's confidence and expectations of their firm's prospective net operating income and future financial performance. Despite tax expensing and deductibility benefits, any debt load-up was not statistically determined to positively influence share prices. The above discussions provide ample impetus for broadening the classical theoretical frameworks typically applied for studying management decision-making in general and capital structure determinations, which are primarily and traditionally framed within the spectrum of rational or irrational decision-making. This study's results have indicated the influence of the behavioural traits of overconfidence and optimism in capital structure determinations, albeit at a lower level of significance for the CEOs/CFOs of sampled Tbks. Further studies are warranted to explore consistent modelling of the influence dynamics among the key variables and determinants, to determine the efficacy of capital structure decisions more precisely. From the capital market perspective, share prices are correlated with a firm's capital structure strategies; certain capital structure determinations-those perceived to contribute to improving a firm's operational and financial performance-are expected to positively influence share price. Overconfident and overly optimistic management (CEOs/CFOs) is generally perceived to have the propensity to embark on investments and/or projects aggressively funded by debt, while moderately confident and temperately optimistic management is expected to rely more on internal sources of funding. However, this study's results show that such behavioural inclinations are not the sole determinants of capital structure decisions that positively impact share prices. Prospects for increased share prices can be presumed to increase when confidently and optimistically driven capital structure decisions are coupled with management's competencies in 1) achieving a desired capital costs structure, 2) sustaining and improving revenue growth trends, 3) stable management of cashflows and 4) implementing effective monitoring and mitigation of operational and financial risks.

Statistical testing results confirm the direct influence of certain demographic attributes—gender, age, education and professional experience—on capital structure determinations.

#### Gender

Prior studies have consistently articulated that 1) female executives rely more on information, data and relevant analysis in their decision-making process; 2) female executives' less optimistic management style entails them being more cautious, risk-averse and conservative in their decision-making; 3) ceteris paribus, female executives prefer to rely on established banking relationships and secure loans to fund projects and for investments thoroughly evaluated to contribute net-positive returns and improve their firm's growth trends; and 4) female executives appear to favour lower leveraged capital structures and are not fixated on achieving optimal capital structure (see Bellucci et al., 2010; Maurice et al., 2013; Mara et al., 2016; Adusei & Obeng, 2019; Đang et al., 2020; Schopohl et al., 2020; Benkraiem et al., 2021; Sudip et al., 2021). The present study found that gender (as a component of demographic attributes) is a key determinant of capital structure. Female executives display lower levels of overconfidence and are more cautious, less optimistic, more risk-averse and more focused on managing and avoiding financial risks, instead of purely endeavouring to achieve optimal capital structure. Female managers (CEOs/CFOs) who have held these roles/positions for long periods appear to be more risk-tolerant and aggressive in their capital structure determinations.

# Age

The influence of age (as a demographic attribute) on capital structure determinations has been widely researched. Older managers/executives are typically found to prefer more moderate, conservative and cautious capital structure strategies, compared to younger executives who prefer aggressive leveraged models and are more tolerant of project and portfolio risks (Tibor et al., 2012; McGuinness, 2020). The present study's findings agree with this. As previously discussed, past experiences with challenging externalities (market and financial shocks and crises) and lengthy and costly adjustments had affected older sampled managers (CEOs/CFOs), leading them to adopt more cautious approaches in determining capital structure compositions.

#### Education and professional experience

The present study notes a positive correlation between education (as a component of demographic attributes) and leverage ratio. Nevertheless, it is also noted that highly educated managers (CEOs/CFOs) who possess significantly high levels of overconfidence have the propensity to favour a lower leveraged capital structure composition. Sampled managers (CEOs/CFOs) possessing both education and previous career experience in fields related to corporate finance, accounting, economics, mathematics, statistics and data analytics) appear to be more aggressive with debt loading, maintain a lower balance of cash-at-hand and are more prone to engage in debt repurchase strategies. This is consistent with Custódio and Metzger's (2014) finding that managers (CEOs/CFOs) with relevant experience and training tend to opt for more aggressive capital structure strategies. Survey responses indicate that sampled managers (CEOs/CFOs) with higher education levels tend to adopt a more active financial management strategy, paying greater attention to project- and investment-level funding costs while ensuring their selected capital structure is less exposed to potential volatility in cash flows. They also showed comparatively higher confidence in being able to secure external funding, even during periods of tight liquidity. Financially trained executives (CEOs/CFOs) appeared to be more closely involved in the setting of dividend policy and focused on the impacts of relevant fiscal and taxation regulations. More experienced and technically trained executives (CEOs/CFOs) were predominantly employed by larger Tbks. It is reasonable to suggest that managers (CEOs/CFOs) with greater technical competency and experience in corporate financial and financial management would adopt more rigorous evaluation and assessment in decision-making, and rely less on behavioural and heuristic tendencies and guesswork or 'feel'.

# Potential Confounders: 'Anomalies' and 'Disturbances'

The proposed model adopted to test the underlying relationships between selected capital structure determinants and the dependent variable (D) did not statistically validate the relevant classical frameworks' discourses on optimal capital structure. Where direct influences were found between the determinant variables and dependent capital structure variables, their significance was inconsistent. A possible explanation for this is the existence of 'anomalies' and 'disturbances' that might have impacted the relationships more significantly than the selected determinants. External occurrences and events beyond the control of and unanticipated by capital structure decision-makers (e.g., external economic shocks, financial crises, market turmoil and sharp currency depreciations) would act as anomalies and disturbances that might upend the stability, consistency and direction of the influence dynamics within the modelled relationship. In practical terms, such anomalies and disturbances would prevent management from achieving optimal capital structure decisions. Management, in turn, is required to adopt rectifying adjustments. The 'speed of adjustment' and 'adjustment costs' would differ depending

on the characteristics of the affected variables, underlying type and dynamics of the relationship, and significance of the 'disturbance' by the anomalies.
