| Article history: Received 28 Februrary 2019 Accepted 23 September 2019 Available online 23 September 2019 Keywords: Shell finite element Modeling Rotation degree of freedom Junction Solid-shells | The study of structures in engineering solid mechanics is very often requires the modeling of complexes structures composed of two parts of thin and thick structure elements. As examples is associated with the case of stiffener under a dome and the cooling tower of the nuclear power which is supported on massive supports. In the numerical analysis, this imposes the connection between two different types of finite elements, two dimensional element for thin structures and three-dimensional elements for solid structures. Knowing that solid finite elements contain only translational degrees of freedom, whereas the finite elements of thin shells includes nodal variables of rotations, and then the number of degrees of freedom are not compatible in the junction zone between these two types of structures. This obviously causes great difficulty in solving the problem numerically. The objective of this work is to present the development of a shell finite element with no degree of freedom of rotation that can be used for the modeling of these two different types of structures and the results obtained are very encouraging. |

1. Introduction

Among the modeling problems existing in the study of structures using finite elements, we find the question relating to the connection of finite elements of the shell type with solid elements, indeed the number of degrees of freedom in the connection zone of the elements is not identical. The solid element has three translations while the shell element has three translations plus three rotations. In the literature there exist a some number of finites elements which are conceived to solve this type of problems, as an example the solid-shell element type which have shell behavior; but with a three-dimensional geometry. These elements allow combining characteristics of solid elements such as the geometrical description and the degrees of freedom to the mechanical models which uses the theories of the shells. Among these elements, the three dimensional shell elements and are based on isoparametric solid elements and having only two nodes according to the thickness direction. Another shell element with hexahedral geometry named SHB8PS developed by Abed-Meraim and Combescure (2002), this solid element is derived from a purely three-dimensional formulation and can be used to model thick shells. Hamadi (2006) developed a parallelepiped element named SBP8C and based on the strain approach formulations, it can be used for

© 2020 Growing Science Ltd. All rights reserved. doi: 10.5267/j.esm.2019.9.006 modeling the three dimensional structures and also for the problems of bending of the thin and thick plates, the results are very acceptable.

Contrary to solid-shell element which can be used for analyzing thin and thick structures, there are two dimensional shell elements without degrees of freedom of rotation and can be used to model only the thin parts of the structure for connection in the zone of junction between thin and thick structures. In addition to the advantage of the coherence of the degrees of freedom between the shell elements and solids, these elements have less number of degrees of freedom than other solid elements and do not suffer from locking shear-bending phenomenon. These elements also present the advantageous conditioning of stiffeners matrix which improves as the thickness decreases. As an example of these type of elements, the DKTRF element (Guo et al., 2002) which is obtained by derivation from the triangular element DKT12 (Batoz & Dhatt, 1992) where the rotations of the inside nodes are expressed in the terms of the eighteen translation degrees of per node. Another element called S3 formulated by Crisfield and Peng (1992) and then is more improved by Sabourin and Brunet (2006), it constructed starting from the triangular element of Morley (1971) and Oñate et al. (1989) is introduced the Bending into a triangular element of membrane without addition the rotation degree of freedom. This strategy was developed and used by Rio et al. (1993) like Brunet and Sabourin (1994, 1995). Mercier (1998) used the triangular element DKT12 obtained by superposition of elements CST and DKT6, the obtained element takes into account both membrane and bending effects without degrees of rotations., i.e. the three medium side rotations of the element DKT6 are eliminated. Finally, we should mention that other finite elements of shells types without rotations are published by Oñate and Flores (2005) and Oñate et al. (2007).

This paper presents the formulation of a triangular finite element called DKT18RF, is a shell type element without rotation degree of freedom and is obtained by derivation from the flat shell element DKT18 developed by Batoz and Dhatt (1992). This element is the result of the superposition of the triangular element of membrane CST which contains two degrees of freedom per node and the plate bending element DKT which contains three degree of freedom per node, two rotations and one vertical deflection. The principal idea in this work consists of modifying the deformation matrix expresses the bending effects of DKT element; so that it does only contain the terms represent the bending effect. The superposition of element DKT modified with the membrane CST element gives the called DKT18RF finite element with only three translations per node. This element is programmed under MATLAB in order to test its performance and efficiency through the different test available in the literature.

2. Formulation of DKT18RF element

While basing on the triangular element of type flat shell element DKT18, which is constructed by superposition of membrane element CST includes two in plane degrees of freedom (U, V) as nodal variables, and the discrete Kirchhoff element DKT which has three nodal variables (W, θx , θy). By addition of a fictitious in plane rotation θz , and after assembling these two elements to obtains a flat shell element with the three translation displacements (U, V, W) and three nodal rotations ($\theta_X, \theta_Y, \theta_Z$) around the axes X, Y and Z, respectively, we will formulate the triangular element called DKT18RF. Following the same procedure of superposition procedure, the membrane part is represented by the linear element CST which contains the nodal variables (U, V), and the bending part by the element DKT contains only lateral nodal variable (W). This superposition is illustrated in Fig. 1.

Fig. 1. Construction of DKT18RF element after elimination of rotations

2.1 Definition of the local system reference coordinates

The surface of reference of the element is defined by

$$\{\mathbf{x}_{p}\} = \begin{cases} \mathbf{X} \\ \mathbf{Y} \\ \mathbf{Z} \end{cases} = \sum_{i=1}^{3} N_{i} \begin{cases} \mathbf{X}_{i} \\ \mathbf{Y}_{i} \\ \mathbf{Z}_{i} \end{cases}$$
(1)

The interpolation functions N_i are given by

$$N_1 = \lambda = 1 - \xi - \eta$$
 , $N_2 = \xi$, $N_3 = \eta$ (2)

The basic vectors a₁ and a₂ are

$$\{a_1\} = \{x_{p,\xi}\} = \begin{cases} X_{21} \\ Y_{21} \\ Z_{21} \end{cases}, \{a_2\} = \{x_{p,\eta}\} = \begin{cases} X_{31} \\ Y_{31} \\ Z_{31} \end{cases}$$
(3)

The local axes reference can be defined as

$$[\mathbf{Q}] = \begin{bmatrix} \mathbf{t}_1 & \mathbf{t}_2 & \mathbf{n} \end{bmatrix} \tag{4}$$

$$n = \frac{a_1 \wedge a_2}{|a_1 \wedge a_2|} , \quad t_1 = \frac{a_1}{L_{21}} , \quad t_2 = n \wedge t_1$$
(5)

$$L_{21} = (X_{21}^2 + Y_{21}^2 + Z_{21}^2)^{\frac{1}{2}}$$
(6)

Where

$$X_{21} = X_2 - X_1 , Y_{21} = Y_2 - Y_1 , Z_{21} = Z_2 - Z_1$$
(7)

154

$$\{n\} = \begin{cases} n_X \\ n_Y \\ n_Z \end{cases} = \frac{1}{2A} \begin{cases} Y_{21}Z_{31} - Y_{31}Z_{21} \\ Z_{21}X_{31} - Z_{31}X_{21} \\ X_{21}Y_{31} - X_{31}Y_{21} \end{cases}$$
(8)

The surface of element A

$$2A = ((Y_{21}Z_{31} - Y_{31}Z_{21})^2 + (Z_{21}X_{31} - Z_{31}X_{21})^2 + (X_{21}Y_{31} - X_{31}Y_{21})^2)^{\frac{1}{2}}$$
(9)

 t_1 and t_2 can be also calculated by

$$\langle \mathbf{t}_1 \rangle = \langle \mathbf{n}_Z + \frac{\mathbf{n}_Y^2}{a} \quad \frac{-\mathbf{n}_X \mathbf{n}_Y}{a} \quad -\mathbf{n}_X \rangle \tag{10}$$

$$\langle \mathbf{t}_2 \rangle = \langle \frac{-\mathbf{n}_X \mathbf{n}_Y}{\mathbf{a}} \quad \mathbf{n}_Z + \frac{\mathbf{n}_X^2}{\mathbf{a}} \quad -\mathbf{n}_Y \rangle \tag{11}$$

where

$$a = 1 + n_Z \tag{12}$$

The point q in the thickness is defined by

$$\{x_q\} = \{x_p\} + Z\{n\}$$
(13)

The coordinates of nodes 1, 2, 3 in the local system at original 1 are

$$\begin{cases} x_1 \\ y_1 \end{cases} = \begin{cases} 0 \\ 0 \end{cases} , \qquad \begin{cases} x_2 \\ y_2 \end{cases} = \begin{bmatrix} t_1 & t_2 \end{bmatrix}^T \begin{cases} X_{21} \\ Y_{21} \\ Z_{21} \end{cases} , \begin{cases} x_3 \\ y_3 \end{cases} = \begin{bmatrix} t_1 & t_2 \end{bmatrix}^T \begin{cases} X_{31} \\ Y_{31} \\ Z_{31} \end{cases}$$
(14)

The coordinates of a point p at middle surface are

$$\{\mathbf{x}_{\mathbf{p}}\} = \begin{cases} \mathbf{x}_{\mathbf{y}} \\ \mathbf{y} \end{cases} = \sum_{i=1}^{3} N_{i} \begin{cases} \mathbf{x}_{i} \\ \mathbf{y}_{i} \end{cases}$$
(15)

Expression of virtual internal work W^e results from the membrane and bending effect in the local reference system

$$W_{int}^{e} = W_{int}^{m} + W_{int}^{f} = \int \langle e^* \rangle N dA + \int \langle \chi^* \rangle M dA$$
(16)

2.2 Kinematic variables

The displacement field of a point q is defined by

$$u_{q}^{*} = u_{p}^{*} + z\beta^{*}$$
, $\frac{-h}{2} \le z \le \frac{h}{2}$ (17)

Where h is the thickness of the shell, and β the rotation

$$\begin{cases} u_q^* \\ v_q^* \\ w_q^* \end{cases} = \begin{cases} u^* \\ v^* \\ w^* \end{cases} + z \begin{cases} \beta_x \\ \beta_y \\ 0 \end{cases}$$
(18)

Displacements of membrane obtained by CST element

$$u^* = \langle N_u \rangle \{u_n^*\} \quad , \quad v^* = \langle N_u \rangle \{u_n^*\} \tag{19}$$

 $\{u_n^{\,*}\}$ vector of the nodal variables of the element

$$\{u_n^*\} = \langle \cdots (u_i^* \quad v_i^* \quad w_i^*) \cdots i \text{ vary from 1 to 3} \rangle$$
(20)

Rotations βx and βy relating to element DKT are

$$\beta_{x} = \langle N_{x} \rangle \{u_{n}^{*}\} \quad , \quad \beta_{y} = \langle N_{y} \rangle \{u_{n}^{*}\}$$
(21)

2.3 Membrane deformations

The virtual membrane deformations in terms of nodal displacements are given by

$$\{e^*\} = [B_m]\{u_n^*\}$$
(22)

$$\{e^*\} = \begin{cases} u_{,x}^* \\ v_{,y}^* \\ u_{,y}^* + v_{,x}^* \end{cases}$$
(23)

Where

$$[B_{m}] = \frac{1}{2A} \begin{bmatrix} y_{3} \langle N_{u,\xi} \rangle - y_{2} \langle N_{u,\eta} \rangle \\ -x_{3} \langle N_{v,\xi} \rangle + x_{2} \langle N_{v,\eta} \rangle \\ -x_{3} \langle N_{u,\xi} \rangle + x_{2} \langle N_{u,\eta} \rangle + y_{3} \langle N_{v,\xi} \rangle - y_{2} \langle N_{v,\eta} \rangle \end{bmatrix}$$
(24)

$$N_{u} = \langle \cdots N_{i} \quad 0 \quad 0 \dots i \text{ vary from 1 to 3} \rangle$$
(25)

$$N_{v} = \langle \cdots 0 \quad N_{i} \quad 0 \dots i \text{ vary from 1 to 3} \rangle$$
(26)

$$[B_{m}] = \frac{1}{2A} \begin{bmatrix} -y_{3} + y_{2} & 0 & 0 & y_{3} & 0 & 0 - y_{2} & 0 & 0 \\ 0 & x_{3} - x_{2} & 0 & 0 & -x_{3} & 0 & x_{2} & 0 \\ x_{3} - x_{2} & -y_{3} + y_{2} & 0 - x_{3} & y_{3} & 0 & x_{2} - y_{2} & 0 \end{bmatrix}$$
(27)

2.4 Bending deformation

Virtual curvatures

$$\{\chi^*\} = [B_f]\{u_n^*\}$$
(28)

$$\{\chi^*\} = \begin{cases} \beta^*_{x,x} \\ \beta^*_{y,y} \\ \beta^*_{x,y} + \beta^*_{y,x} \end{cases}, [B_f] = \frac{1}{2A} \begin{bmatrix} y_3 \langle N^x_{,\xi} \rangle - y_2 \langle N^x_{,\eta} \rangle \\ -x_3 \langle N^y_{,\xi} \rangle + x_2 \langle N^y_{,\eta} \rangle \\ -x_3 \langle N^x_{,\xi} \rangle + x_2 \langle N^x_{,\eta} \rangle + y_3 \langle N^y_{,\xi} \rangle - y_2 \langle N^y_{,\eta} \rangle \end{bmatrix}$$
(29)

In the vectors N only the terms of the bending are considered (the terms of rotation are null)

$$N^{x} = \langle 0 \quad 0 \quad N_{11}^{x} \quad 0 \quad 0 \quad N_{21}^{x} \quad 0 \quad 0 \quad N_{31}^{x} \rangle$$
(30)

$$N^{y} = \langle 0 \quad 0 \quad N^{y}_{11} \quad 0 \quad 0 \quad N^{y}_{21} \quad 0 \quad 0 \quad N^{y}_{31} \rangle$$
(31)

 $N^x{}_{11}\;N^x{}_{21}\;N^x{}_{31}$ and $N^y{}_{11}\;N^y{}_{21}\;N^y{}_{31}$ are given by

$$N_{i1}^{x} = \frac{3}{2L_{k}}P_{k}C_{k} - \frac{3}{2L_{m}}P_{m}C_{m} , \quad N_{i1}^{y} = \frac{3}{2L_{k}}P_{k}S_{k} - \frac{3}{2L_{m}}P_{m}S_{m}$$
(32)

The indices of k and m are relative to the two sides having the summit i common point are given by Table 1, P_k and P_m are defined by Table 2.

Table 1. Indices k and m

| | Summit Nodes i | Side k (i-j) | Side m (i-j) |
|--------|----------------|--------------|--------------|
| n A | 1 | 4 (1-2) | 6 (3-1) |
| 6 - <5 | 2 | 5 (2-3) | 4 (1-2) |
| | 3 | 6 (3-1) | 5 (2-3) |

Table 2. Values of P_K and P_m

| | $\mathbf{P}_{\mathbf{k}}$ |
|---------------------------|---------------------------|
| ባ 🛦 | (k= 4 to 6) |
| 3 | P4=4 $\xi \lambda$ |
| 6 - ~ 5 | Ρ5=4 ξη |
| $1 \xrightarrow{4} 2 \xi$ | Ρ6=4λη |

$$C_{k} = \frac{x_{ij}}{L_{k}}$$
, $S_{k} = \frac{y_{ij}}{L_{k}}$, $L_{k} = (x_{ij}^{2} + y_{ij}^{2})^{\frac{1}{2}}$ (33)

2.5 The internal work

$$W_{\text{int}}^{\text{e}} = \langle u_n \rangle [K] \{ u_n \}$$
(34)

The stiffness matrix is

$$[K] = [K_m] + [K_f]$$
(35)

$$[\mathbf{K}_{\mathbf{m}}] = \mathbf{A}[\mathbf{B}_{\mathbf{m}}]^{\mathrm{T}}[\mathbf{H}_{\mathbf{m}}][\mathbf{B}_{\mathbf{m}}]$$
(36)

$$[K_f] = A[B_f]^T[H_f][B_f]$$
(37)

where H_m and H_f : matrix of homogenized behavior of membrane and bending effects

$$[H_{\rm f}] = \frac{{\rm E}h^3}{12(1-\nu^2)} \begin{bmatrix} 1 & \nu & 0 \\ \nu & 1 & 0 \\ 0 & 0 & \frac{1-\nu}{2} \end{bmatrix}$$
(38)

$$[H_{\rm m}] = \frac{\rm Eh}{(1-\nu^2)} \begin{bmatrix} 1 & \nu & 0\\ \nu & 1 & 0\\ 0 & 0 & \frac{1-\nu}{2} \end{bmatrix}$$
(39)

E and v are respectively the Young modulus and the Poisson's ratio, the resulting normal force and bending moment are

$$[N] = [H_m] \{e\} , \ [M] = [H_f] \{\chi\}$$
(40)

3. Results and Discussion

To test the efficiency and the performance of the developed element DKT18RF, the following various cases of applications in the field of the structures are performed.

3.1. Clamped cylindrical shell with rigid diaphragm

The clamped cylindrical shell shown in Fig. 2 is subjected to two diametrically opposed concentrated loads, and supported by two rigid diaphragms. The details of the geometry, loadings, materials, the boundary and symmetry conditions are given in the same figure. This test case is frequently used to evaluate the behavior of the shell finite element for simulated complex membrane states with a significant share of bending without the extension of the average surface. One-eighth of the shell is modeled by the finite element DKT18RF by using a regular mesh elements N = 2, 4, 6. The displacements W_C and V_D at points C and D are given in Tables 3 and 4 respectively. The results obtained are compared with the reference solution given by Lindberg et al. (1969) and those of elements DKT12 and DKT18 cited above. Fig. 3 shows the deformed shape of the cylinder under the applied loading.

Fig. 3. Deformed shape of the clamped cylindrical shell (meshes 6x6)

The analysis of the results obtained by element DKT18RF for this case test shows a monotonous convergence of the vertical displacements at the point C. This result shows the good performance for this element.

3.2 Pinched cylinder with free edges

Another test case widely used to study the shell finite elements is that of the pinched cylinder with free edge. This case test makes it possible to evaluate the convergence, performances and the representation of the rigid body mode. One-eighth of the shell is studied by the element DKT18RF with different types of mesh, the geometry, the characteristics of the material as well as the boundary conditions and symmetries are exposed in Fig. 4, where can distinguish two different cases of loading and thickness. The vertical displacement results Wc at point C are reported in Tables 5 and 6 are compared with the reference solution given by Macneal and Harder (1985) as well as the results obtained by other finite elements (Hamadi et al., 2016; Belarbi, 2000; Cantin & Clough, 1968; Bogner et al., 1967;

Ashwell & Sabir, 1972; Sabir & Lock, 1972). Fig. 5 shows the deformed shape of pinched cylinder with free edges.

The results obtained by the DKT18RF element can be considered satisfactory for both cases. The convergence of the element towards the reference solution can be guaranteed by refining the meshes.

Fig. 5. Deformed shape of pinched cylinder with free edges (meshes 3×9)

Fig. 6. Cantilever beam subjected to a point load its free end

3.3 Cantilever beam

A cantilever beam is clamped at one end and charged at the other free end as shown in Fig. 6. The values of the load, Young modulus, Poisson's ratio and the thickness are given on the same figure. This case test is a standard problem to test the efficiency of the finite elements (Macneal & Harder, 1985).

Fig. 7 shows the results obtained for the deflection at point A. These values are calculated by the use of different meshes with the DKT18RF element and are compared with the reference solution (Macneal & Harder, 1985) and with other finite elements Q4 (the standard four-node isoparametric element), and Q4SBE1 (Hamadi, 2006), SBRIE (Sabir & Salhi, 1986), SBRIE2 (Sabir & Sfendji, 1995). It can be observed that the convergence is monotone and the closed form solution can be obtained with the increased number of elements used. The deformed shape of the cantilever beam is represented in Fig. 8.

Fig. 7. Curve of convergence of displacement at the point A

Fig. 7 shows the monotone convergence curve of the element DKT18RF and good results can be obtained with the increased number of meshes.

Fig. 8. Deformed shape of a cantilever beam (meshes 1x6)

4. Conclusion

In this paper the developed rotation free shell finite element is presented. The formulated element is obtained by using superposition of the membrane element CST with constant deformations and the modified discrete Kirchhoff element DKT. The modified element have only one translation nodal variable (w), which endow with a shell finite element with three translations per node (u, v, w). The good performance of formulated element DKT18RF is examined through the validation tests presented in part 3 of this paper.

Monotonous convergence towards the reference solution was clearly observed. The absence of rotation does not affect on the quality of the results obtained, even so it is remarkable in case tests 2 and 3 that it is required to refined meshes to obtain the closed form solution. Besides of convergence is slow, we can say that the element remains always effective considering it is conceive mainly to solve the problem of connection in the zone of junction between the thin and thick structures.

Finally, from this work we can see in perspective the idea of formulation a finite shell type element usable for thin and thick structures from the element DKT18RF.
